Useful atomistic simulations in the condensed phase require accurate depictions of solvent. While experimental measurements of fundamental physical properties offer a straightforward approach for evaluating forcefield quality, the bulk of this information has been tied up in formats that are not machine-readable. These formats require substantial human effort to compile benchmark datasets which are prone to accumulation of human errors, hindering the development of reproducible benchmarks of forcefield accuracy. Here, we examine the feasibility of benchmarking atomistic forcefields against the NIST ThermoML data archive of physicochemical measurements, which aggregates thousands of experimental measurements in a portable, machine-readable, self-annotating format. As a proof of concept, we present a detailed benchmark of the generalized Amber small molecule forcefield (GAFF) using the AM1-BCC charge model against measurements (specifically liquid densities and static dielectric constants at ambient pressure) automatically extracted from the archive, and discuss the extent of available data for neat liquids. The results of this benchmark highlights a general problem with fixed-charge forcefields in the representation of liquids of low dielectric.

Keywords: molecular mechanics forcefields; forcefield parameterization; forcefield accuracy; forcefield validation; mass density; static dielectric constant

I. INTRODUCTION

Recent advances in hardware and software for molecular dynamics simulation now permits routine access to atomistic simulations at the 100 ns timescale and beyond. [JDC: Cite something here, like the Amber "routine microsecond" paper? http://pubs.acs.org/doi/abs/10.1021/ct400314y]. Leveraging these advances in combination with consumer GPU clusters, distributed computing, or custom hardware has brought microsecond and millisecond simulation timescales within reach of many laboratories. These dramatic advances in sampling, however, have revealed deficiencies in forcefields as a critical barrier to enabling truly predictive simulations of physical properties of biomolecular systems.

Protein and water forcefields have been the subject of numerous benchmarks [1] and enhancements [2–4], with key outcomes including the ability to fold fast-folding proteins [JDC: Cite Pande and Shaw papers?], improved fidelity of water thermodynamic properties [18], and improved prediction of NMR observables. Although small molecule force-fields have also been the subject of benchmarks [5] and improvements [6], such work has typically focused on small perturbations to specific functional groups. For example, a recent study found that modified hydroxyl nonbonded pa-

rameters led to improved prediction of static dielectric constants and hydration free energies [6]. There are also outstanding questions of generalizability of these targeted perturbations; it is uncertain whether changes to the paramesters for a specific chemical moiety will be compatible with seemingly unrelated improvements to other groups. Addressing these questions requires establishing a community agreement on shared benchmarks that can be easily replicated among laboratories to test proposed forcefield enhancements and expanded as the body of experimental data grows.

A key barrier to establishing reproducible and extensi-46 ble forcefield accuracy benchmarks is that many experi-47 mental datasets are heterogeneous, paywalled, and un-48 available in machine-readable formats (although notable 49 counterexamples exist, e.g. the RCSB [7], FreeSolv [8], 50 and BMRB [9]). While this inconvenience is relatively mi-51 nor for benchmarking forcefield accuracy for a single tar-52 get (e.g. water), it becomes prohibitive for studies span-53 ning the relevant chemical space. To ameliorate prob-54 lems of data archival, the NIST Thermodynamics Research 55 Center (TRC) has developed a IUPAC standard XML-based 56 format—ThermoML [10]—for storing physicochemical mea-57 surements, uncertainties, and metadata. Experimental 58 researchers publishing measurements in several journals 59 (J. Chem. Eng. Data, J. Chem. Therm., Fluid Phase Equil., 60 Therm. Acta, and Int. J. Therm.) are guided through a data archival process that involves sanity checks, conversion to a 62 standard machine-readable format, and archival at the TRC 63 (http://trc.nist.gov/ThermoML.html).

Here, we examine the ThermoML archive as a potential source for providing the foundation for a reproducible, extensible accuracy benchmark of biomolecular forcefields.

67 In particular, we concentrate on two important physical property measurements easily computable in many simulation codes—neat liquid density and static dielectric constant measurements—with the goal of developing a standard benchmark for validating these properties in fixedcharge forcefields of drug-like molecules and biopolymer 73 residue analogues. These two properties provide sensitive tests of forcefield accuracy that are nonetheless straightfor-₇₅ ward to calculate. Using these data, we evaluate the generalized Amber small molecule forcefield (GAFF) [11] with the AM1-BCC charge model [12, 13] and identify systematic bi-₇₈ ases to aid further forcefield refinement.

Extracting neat liquid measurements from the NIST TRC ThermoML Archive

We retrieved a copy of the ThermoML Archive from the NIST TRC (http://trc.nist.gov/ThermoML.html accessed 13 Sep 2014) and performed a number of sequential for benchmarking organic molecule forcefields. [JDC: This is the date I had on the ThermoML.tar.gz archive in GitHub. We should check to make sure this is accurate.] As our aim is to explore neat liquid data with functional groups relevant 124 to drug-like molecules, we applied the following ordered filters, starting with all data containing density or static dielectric constants:

- 1. The measured solution contains only a single component (e.g. no binary mixtures)
- 2. The molecule contains only the druglike elements (defined here as H, N, C, O, S, P, F, Cl, Br)
 - 3. The molecule has \leq 10 heavy atoms
 - 4. The measurement was performed in a biophysically relevant temperature range [K] $(270 \le T \le 330)$
 - 5. The measurement was performed at ambient pressure [kPA] $(100 \le P \le 102)$
- 6. Measured densities below 300 kg m $^{-3}$ were discarded to eliminate gas-phase measurements
 - 7. The temperature and pressure were rounded to nearby values (as described below), averaging all 140 measurements within each group of like conditions
 - 8. Only conditions (molecule, temperature, pressure) for which both density and dielectric constants were available were retained

by common data reporting variations; for example, an experiment performed at water's freezing point at ambient 147 pressure might be entered as either 101.325 kPA or 100 kPA, 148 root-mean square (RMS) relative error over all measure-

TABLE I. Successive filtration of the ThermoML Archive. A set of successive filters were applied to all measurements in the ThermoML Archive (accessed 13 Sep 2014) that contained either mass density or static dielectric constant measurements. Each column reports the number of measurements remaining after successive application of the corresponding filtration step.

pressures within the range [kPA] $(100 \le P \le 102)$ were 116 rounded to exactly one atmosphere. Temperatures were 117 rounded to one decimal place. [JDC: Does this reflect the 118 accuracy of reporting ambient temperatures?] The applica-119 tion of these filters (Table I) leaves 245 conditions—where filtering steps to summarize the ThermoML content relevant 120 a condition here indicates a (molecule, temperature, pressure) tuple—for which both density and dielectric data are ₁₂₂ available. The functional groups present in the resulting 123 dataset are summarized in Table II.

> [JDC: It might be useful to point the users to the scripts that were used to do this extraction. Also, can we automate the downloading of the complete up-to-date archive, per-127 haps with Kenneth's help in identifying the least intrusive 128 way to do so?]

B. Benchmarking GAFF/AM1-BCC against the ThermoML Archive

[JDC: If we lead with a Results section before Methods, we 132 have to start with a small summary of the calculation. We 133 should tell readers the salient details—we ran simulations with a small timestep to minimize integrator error, we used stochastic thermal and pressure control, and we used an adaptive simulation scheme that ensured simulations ran long enough to achieve target accuracy. We can also mention that we used OpenMM, but these calculations can easily be adapted to other codes.]

1. Mass density

Mass density has been widely used for parameterizing and testing forcefields, particularly the Lennard-Jones parameters representing dispersive and repulsive interactions [15, 16]. We therefore used the present ThermoML ex-The temperature and pressure rounding step was motivated 145 tract as a benchmark of the GAFF/AM1-BCC forcefield (Fig. 1).

[JDC: Remind readers how mass density is computed.]

Overall, the densities show reasonable accuracy, with a with a temperature of either 273 K or 273.15 K. Therefore all 149 ments of $3\pm0.1\%$ (with one standard error of the mean de-

TABLE II. Functional groups present in filtered dataset. The filtered ThermoML dataset contained 245 distinct (molecule, temperature, pressure) conditions, spanning 44 unique compounds. The functional groups represented in these compounds (as identified by the program checkmol v0.5 [14]) is summarized here.

termined by bootstrapping over all measurements), especially encouraging given that this forcefield was not designed with the intention of modeling bulk liquid properties of organic molecules [11] [JDC: Sig figs issue—this should be 3.x±0.1%.] This is reasonably consistent with previous studies reporting agreement of 4% on a different benchmark set [5]. [JDC: Did that previous study report an uncertainty?]

[JDC: Discuss outliers here. There must be more things we can say about densities. Some of the densities are quite good, while others seem poor, with systematic bias toward higher densities than experiment. We can also point out that densities at different temperatures for a given molecule seem to be biased in a consistent way.]

2. Static dielectric constant

163

As a measure of the dielectric response, the static dielectric constant of neat liquids provides a critical benchmark tric constant of neat liquids provides a critical benchmark of the accuracy electrostatic treatment in forcefield models. We therefore compare simulations against the measurements in our ThermoML extract. Overall, we find the dielectric constants to be qualitatively reasonable, but with clear deviations from experiment. In particular, GAFF/AM1-BCC systematically underestimates the dielectric constants for nonpolar organics, with the predictions of $\epsilon \approx 1.0 \pm 0.05$ being substantially smaller than the measured $\epsilon \approx 2$. Because this deviation likely stems from the lack of electronic polarization, we added a simple empirical correction for polarization [17] that is based on counting the elements in a

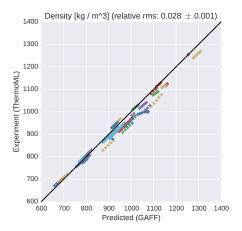

FIG. 1. Comparison of liquid densities between experiment and simulation. Liquid density measurements extracted from ThermoML are compared against densities predicted using the GAFF/AM1-BCC small molecule fixed-charge forcefield. Color groupings represent identical chemical species. Simulation error bars represent one standard error of the mean, with the number of effective (uncorrelated) samples estimated using pymbar. Experimental error bars indicate the standard deviation between independently reported measurements, when available, or author-reported standard deviations in ThermoML entries; for some measurements, neither uncertainty estimate is available. See **Section B** for further discussion of error.

177 molecule:

$$\begin{split} \frac{\alpha}{\mathring{\mathbf{A}}} &= 1.53 n_C + 0.17 n_H + 0.57 n_O + 1.05 n_N + 2.99 n_S + \\ 2.48 n_P &+ 0.22 n_F + 2.16 n_{Cl} + 3.29 n_{Br} + 5.45 n_I + 0.32 \end{split} \tag{1}$$

From the polarizability, one can correct the static dielectric using the following equation (from ref. [18]):

$$\epsilon_{corrected} = \epsilon_{MD} + 4\pi N \frac{\alpha}{\langle V \rangle}$$

A similar polarization correction was used in the development of the TIP4P-Ew water model [18]; however, the need is much greater for the nonpolar organics, as the missing polarizability is the dominant contribution to the static dielectric constant. In the case of water, the Sales polarizability model predicts a dielectric correction of 0.52, while 0.79 was used for the TIP4P-EW model. For comparison, we also applied the same empirical correction to the VirtualChemistry dataset [5, 19] and saw similarly improved agreement with experiment for both the GAFF and OPLS forcefields (Fig. 7).

III. DISCUSSION

A. Fitting Forcefields to Dielectric Constants

cause this deviation likely stems from the lack of electronic polarization, we added a simple empirical correction for polarization, we added a simple empirical correction for polarization [17] that is based on counting the elements in a proper sitting dielectric constants during forcefield palarization [17] that is based on counting the elements in a proper sitting dielectric constants during forcefield palarization [18]. However, a number of authors

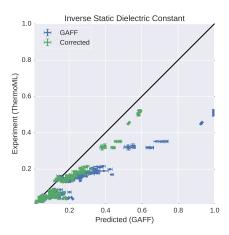

FIG. 2. Measured (ThermoML) versus predicted (GAFF/AM1-BCC) inverse static dielectrics (a). Simulation error bars represent one standard error of the mean estimated via block averaging with block sizes of 200 ps [20]. [JDC: Why are we using block averaging here? Why didn't we just use timeseries.py. We should not be using block averaging, especially without a justification that 200 ps is a reasonable block size for every specific system and condition Let's talk about this.] Experimental error bars indicate the larger of standard deviation between independently reported measurements and the authors reported standard deviations; for some measurements, neither uncertainty estimate is available. See Section B for further discussion of error. The inverse dielectric constant ϵ^{-1} is plotted instead of ϵ because ϵ^{-1} is directly proportional to the Coulomb interaction energy between point charges embedded in a dielectric material [e.g. $U(r) \propto$ $q_1q_2/r \propto \epsilon^{-1}$]. [JDC: We need to trim the whitespace of all sides of the figures that you are outputting in order for the figure to actually fill the column width. There must be some option to set that. See the figure.tight_layout() option in matplotlib, along with matplotlib.backends.backend_pdf.PdfPages.]

have pointed out potential challenges in constructing selfconsistent fixed-charge forcefields [22, 23].

Interestingly, recent work by Dill and coworkers [22] observed that, for CCl₄, reasonable choices of point charges are incapable of recapitulating the observed dielectric of = 2.2, instead producing dielectric constants in the range of $1.0 < \epsilon < 1.05$. This behavior is quite general: fixed point charge forcefields will predict $\epsilon \approx 1$ for many nonpolar or symmetric molecules, but the measured dielectric constants are instead $\epsilon \approx 2$ (Fig. 3). While this behavior is well-known and results from missing physics of polarizability, we suspect it may have several unanticipated consequences. [JDC: Perhaps the free energy of binding to hydrophobic cavities in proteins could be relevant?]

field parameters to match the static dielectric constants of 231 of druglike molecules in cyclohexane. For each molecule in tetrahedrally-symmetric CCl_4 to the asymmetric $CHCl_3$, 233 we took the cavity radius a to be the half the maximum init suddenly becomes possible to achieve the observed di- $_{234}$ teratomic distance and calculated $\mu = \sum_i q_i r_i$ using the electric constant of 4.8 by an appropriate choice of point 235 provided mol2 coordinates and AM1-BCC charges. This calcharges. However, the model for CHCl₃ uses fixed point 236 culation predicts a mean error of -0.9 ± 0.07 kcal / mol for 214 charges to account for both the permanent dipole moment 237 the 643 molecules (where the standard error is computed

206

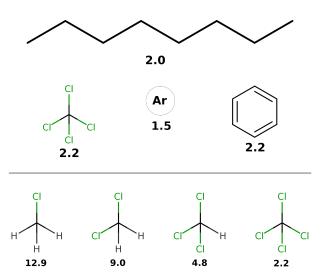

FIG. 3. Typical experimental static dielectric constants of some **nonpolar compounds.** (a). Measured static dielectric constants of various nonpolar or symmetric molecules [?]; fixed-charge forcefields give $\epsilon \approx 1$ for each species. (b). A congeneric series of chlorosubstituted methanes have static dielectric constants between 2 and 13. [Can we use a better citable source for these numbers instead of Wikipedia? Also, what temperatures/pressures are these measurements cited at? Maybe we can just say "near ambient"?] [JDC: We should not use PNG files for figure graphics—only vector graphics (when possible). Can you use a vector graphics PDF instead?] [JDC: Can we show both experimental and GAFF/AM1-BCC computed dielectric constants for some of these compounds?]

216 contains no treatment of polarizability. We hypothesize that this inconsistency in parameterization may lead to strange mismatches, where symmetric molecules (e.g. benzene and CCl₄) have qualitatively different properties than closely related asymmetric molecules (e.g. toluene and CHCl_3).

How important is this effect? As a possible real-world example, we imagine that the missing atomic polarizability could be important in accurate transfer free energies involving low-dielectric solvents. The Onsager model for 225 the transfer free energy of a dipole (Eq. 2) gives an error of $_{226}$ $\Delta\Delta G=\Delta G(\epsilon=2.2)-\Delta G(\epsilon=1)$ of -2 kcal / mol for the transfer of water (a=1.93 Å, $\mu=2.2$ D) into a low dielectric 228 medium such as tetrachloromethane or benzene.

$$\Delta G = -\frac{\mu^2}{a^3} \frac{\epsilon - 1}{2\epsilon + 1} \tag{2}$$

Similarly, we calculated the mean polarization error for Suppose, for example, that one attempts to fit force- 230 solvation free energies (gas to solvent transfer free energies) CCl_4 , $CHCl_3$, CH_2Cl_2 , and CH_3Cl . In moving from the 222 the FreeSolv database [8] [JDC: Which version of FreeSolv?], $_{215}$ and the electronic polarizability, whereas the CCl_4 model $_{238}$ from bootstrapping over measurements), suggesting that 239 the missing atomic polarizabilty unrepresentable by fixed 290 https://github.com/choderalab/ThermoPyL) like molecules.

245 stants have high potential utility as primary data for force- 296 object via PyXB 1.2.4 (http://pyxb.sourceforge.net/). izability, the inconsistency of fixed-charge models in low- 299 Section II A. dielectric media is sufficiently alarming to motivate further study of polarizable forcefields. In particular, continuum methods [24–26], point dipole methods [27, 28], and 300 Drude methods [29, 30] have been maturing rapidly. Finding the optimal balance of accuracy and performance remains an open question; however, the use of experimentallyparameterized direct polarization methods [31] may provide 256 polarizability physics at a cost not much greater than fixed 257 charge forcefields.

ThermoML as a data source

258

284

The present work has focused on the neat liquid density and dielectric measurements present in the ThermoML Archive [10, 32, 33] as a target for molecular dynamics forcefield validation. While liquid mass densities and static dielectric constants have already been widely used in forcefield work, several aspects of ThermoML make it a unique resource for the forcefield community. First, the aggregation, support, and dissemination of ThermoML datasets through the ThermoML Archive is supported by NIST, whose mission makes these tasks a long-term priority. Second, the ThermoML Archive is actively growing, through partnerships with several journals, and new experimental measurements published in these journals are critically examined by the TRC and included in the archive. [JDC: Is the number of journal here also expanding?] Finally, the files 274 in the ThermoML Archive are portable and machine read-275 able via a formal XML schema, allowing facile access to hundreds of thousands of measurements. Numerous additional physical properties contained in ThermoML—including activity coefficients, diffusion constants, boiling point temperatures, critical pressures and densities, coefficients of expansion, speed of sound measurements, viscosities, excess molar enthalpies, heat capacities, and volumes—for neat phases and mixtures represent a rich dataset of high utility for forcefield validation and parameterization.

METHODS

ThermoML Processing

A tarball archive of the ThermoML Archive was 338 obtained from the the NIST TRC on 13 Sep 2014. To explore the content of this archive, 289 ated a Python (version 2.7.9) tool (ThermoPyl: 340

that point charge forcefields could contribute substantially to er- 291 formats the XML content into a spreadsheet-like format rors in predicted transfer and solvation properties of drug- 292 accessible via the Pandas (version 0.15.2) library. First, we 293 obtained the XML schema (http://media.iupac.org/ Given their ease of measurement and direct connection to 294 namespaces/ThermoML/ThermoML.xsd) defining the laylong-range electrostatic interactions, static dielectric con- 295 out of the data. This schema was converted into a Python field parameterization efforts. Although this will require the 297 Finally, this schema and Pandas was used to extract the use of forcefields with explicit treatment of atomic polar- 298 data and apply the successive data filters described in

Simulation

Using an automated tool, boxes of 1000 molecules 302 were constructed using PackMol [34] [JDC: Which AM1-BCC [12, 13] charges were gener-303 version?]. ated using OpenEye Toolkit 2014-6-6 [35], using the 305 oequacpac.OEAssignPartialCharges module with the 306 OECharges_AM1BCCSym option, which utilizes a confor-307 mational expansion procedure prior to charge fitting to minimize artifacts from intramolecular contacts. selected conformer was then processed using antechamber in AmberTools 14 [36]. The resulting AMBER files were converted to OpenMM [37] ffxml forcefield XML files. Simu-312 lation code used libraries gaff2xml 0.6, TrustButVerify 0.1, 313 OpenMM 6.2 [37], and MDTraj 1.2 [38]. [TODO: Provide a script to install all of these versions via conda.]

Molecular dynamics simulations were performed with 316 OpenMM 6.2 [37] using a Langevin integrator (with collision $_{317}$ rate 1 ps $^{-1}$) and a 1 fs timestep, as we found that timesteps of 318 2 fs timestep or greater led to a significant timestep dependence in computed equilibrium densities (Table III). [JDC: 320 Cite Langevin integrator used in OpenMM.] Pressure control to 1 atm was achieved with a Monte Carlo barostat uti-322 lizing molecular scaling and automated step size adjustment during equilibration, with volume moves attempted every 25 steps. The particle mesh Ewald (PME) method [39] was used with a long-range cutoff of 0.95 nm and a long-³²⁶ range isotropic dispersion correction. [JDC: Can we report 327 the automatically-selected PME parameters to aid repro-328 ducibility in other codes?] Simulations were continued un- $_{329}$ til density standard errors were less than 2×10^{-4} g / mL, 330 as estimated using the equilibration detection module in pymbar 2.1 [40]. Trajectory analysis was performed using OpenMM [37] and MDTraj [38]. [JDC: Which versions?] Instantaneous densities were stored every 250 fs, while trajectory snapshots were stored every 10 ps. [JDC: Did we plan to make this data available somewhere, or is it sufficient to put 336 out the scripts?]

CONCLUSIONS

- ThermoML is a potentially useful resource for the forcefield community
- We have curated a subset of the ThermoML Data

Archive for neat liquids with druglike atoms, with thousands of densities and hundreds of dielectrics

TABLE III. Timestep dependence in computed equilibrium density of butyl acrylate. To probe the systematic error from finite timestep integration, we examined the timestep dependence of butyl acrylate density. The number of effective samples was estimated using pymbar's statistical inefficiency routine [40]. To approximate the timestep bias, we compare the density expectation ($\langle \rho \rangle$) to values calculated with a 0.5 fs timestep. We find a 2 fs timestep leads to systematic biases in the density on the order of 0.2%, while 1fs reduces the systematic bias to less than 0.1%—we therefore selected a 1 fs timestep for the present work, where we aimed to achieve three digits of accuracy in density predictions. [JDC: I've reformatted this table a bit, paying more attention to sig figs. I think this might actually be better presented as a figure showing the timestep dependence, perhaps for 4 or 5 timesteps from 0.5 to 2.5 fs, rather than just 3.]

FIG. 5. Comparison of simulated and experimental densities for all compounds. Measured (blue) and simulated (green) densities are shown in units of kg/m³.

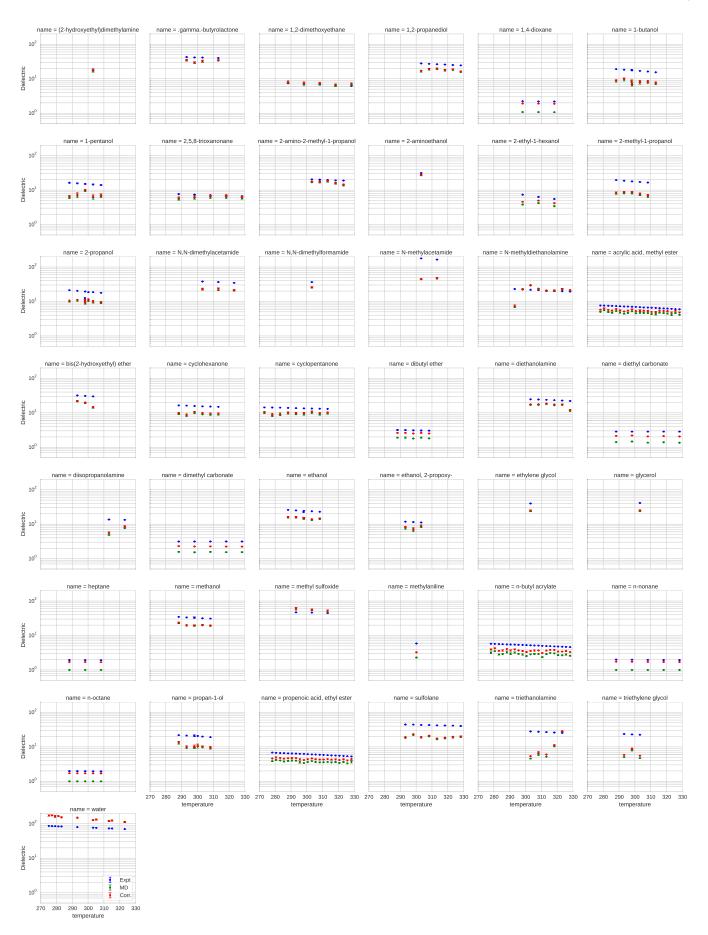

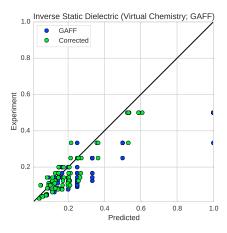

FIG. 6. Comparison of simulated and experimental static dielectric constants for all compounds. Measured (blue), simulated (green), and polarizability-corrected simulated (red) static dielectric constants are shown for all compounds. Note that dielectric constants, rather than inverse dielectric constants, are plotted here.

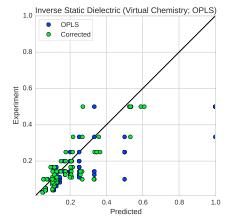

FIG. 7. Atomic polarizability corrections for the Virtual Chemistry dataset. A comparison of measured (*blue*) and simulated dielectric constants from the Virtual Chemistry dataset [5, 19]. with (*red*) and without (*green*) atomic polarizability corrections are shown. [JDC: What from the Virtual Chemistry dataset did we end up using? The computed values? The parameterized files? Since the story is about the ThermoML Archive, do we really want this here, or do we just want to do a comparison between our computed results for some molecules and the Virtual Chemistry results as a validation or sanity check on our computational pipeline?]
